Project's overview:

Nowadays, it is important to complete tasks within a certain time frame, but some human factors do not allow you to complete them all or lose in time. In this regard, the idea was put forward to create an application that will help not to forget and remind all the tasks that need to be done on time.

1) What we did?

- General initialization of directories;

- created "server" file to start the HTTP server;

- created "user" and "todo" file to store the structures of user etc.

In "cmd" directory (the main package):

- created "main" file for starting the whole project.

In "pkg/handler" directory (the package for the logic of app):

- created "handler" file to store routes through key slashes;

- created "auth" file to assign "sign-in" and "sign-up" to routes;

- created "list" and "item" file to do the various operations for user with lists and items.

2) Future plans

For the next steps, it is worth implementing a dependency between interfaces, as well as creating services that will combine interfaces and access the database.
